Problem Set #1

INSERT YOUR NAME HERE

insert date here

Grade /20

Overview

Welcome to Introduction to Programming and Data Management using R! This problem set is intended to give you some practice becoming familiar with using R. In this problem set, we are asking you to: create an R project; knit to pdf; load and investigate an R data frame that is stored on the web; apply some basic functions to atomic vectors; and create a GitHub issue.

• Note: Change the values of the YAML header above to your name and the date.

Question 1: Creating an R project

/2 pts

Create an R project

- Create a folder where you want to save files associated with problem set 1. Let's call that folder "problemset1", but you can name it whatever you want.
 - For instance, it could be EDUC260a » problem_sets » problemset1.
- In RStudio, click on "File" » "New Project" » "Existing Directory" » "Browse".
- Browse to find and select your problem set 1 folder.
- Click on "Create Project".
 - An R project file has the extension ".Rproj".
 - The name of the file should be "problemset1.Rproj", or whatever you named the folder.

Save this problemset1.Rmd file anywhere in the folder named problemset1.

- \bullet Use this naming convention "lastname_firstname_ps#" for your .Rmd files (e.g. jaquette_ozan_ps1.Rmd).
 - If you want, you can change the name of this file to include your first and last name.
- Run the getwd() function and the list.files() function in the code chunk below.
- What is the output? Why?

getwd() list.files()

Answer: The output are files: "problemset1.Rmd" and "problemset1.Rproj" because these are the files currently saved in the folder where this .Rmd file is saved.

Question 2: Knit to pdf

/1 pts

• At the top of this .Rmd file, type in your first and last name in the appropriate place in the YAML header (e.g. "Joe Bruin").

- in the date field of the YAML header, insert the date within quotations (any date format is fine).
- Now click the "Knit" button near the top of your RStudio window (icon with blue yarn ball) or drop down and select "Knit to PDF".
 - Alternatively you can use the shortcut: Cmd/Ctrl + Shift + k.
 - Note: One goal of this assignment is to make sure you are able to knit to a PDF without running into errors.

Question 3: Load .Rdata directly with url and then investigate the data frame

/7 pts

- 1. This question asks you to load a dataframe by specifying the url() function within the load() function.
- Url link for data frame: https://github.com/anyone-can-cook/rclass1/raw/master/data/recruiting/recruit_ps1_small.Rdata
 - Hint: to load .Rdata use the load() and url() functions because you are using a link. follow this approach: load(url("url_link")).
 - * Note: the url_link is put within quotes.

Load the dataframe within this code chunk below.

#?1.0a.d.

load(url("https://github.com/anyone-can-cook/rclass1/raw/master/data/recruiting/recruit_ps1_small.Rdata

2. Print the data frame df recruiting by typing its name.

df_recruiting

##		state_code	school_type	1	ncessch				name
##	1	AK	public	020000	0100208	Bethel F	Regional	High	School
##	2	AK	public	020000	0100211	Aya	agina'ar	Elitr	naurvik
##	3	AK	public	020000	0100212		Kwigill:	ingok	${\tt School}$
##	4	AK	public	020000	0100213	Nelsor	n Island	Area	${\tt School}$
##	5	AK	public	020000	0300216		Alal	kanuk	${\tt School}$
##	6	AK	public	020000	0300217		Emr	nonak	${\tt School}$
##			ac	ddress		city			
##	1	1006 Ron Ed	dwards Memori	ial Dr	I	Bethel			
##	2		106 Village	e Road	Kong	iganak			
##	3		108 Village	e Road	Kwigil	lingok			
##	4		118 Village	e Road	Tokso	ok Bay			
##	5		9 School	L Road	Ala	akanuk			
##	6		General Del	livery	Er	nmonak			

3. Use the typeof() function to investigate the type of data frame df_recruiting.

typeof(df_recruiting)

```
## [1] "list"
```

4. Apply the length() function to the data frame df_recruiting. What does this output mean in your own words?

length(df_recruiting)

```
## [1] 6
```

Answer: the data frame object df_recruiting has a length of 6, meaning that there are 6 elements in the object.

5. Use the str() function to investigate the structure of the data frame df_recruiting.

```
str(df_recruiting)
## Classes 'tbl_df', 'tbl' and 'data.frame':
                                                  6 obs. of 6 variables:
## $ state_code : chr "AK" "AK" "AK" "AK" ...
## $ school_type: Factor w/ 2 levels "private", "public": 2 2 2 2 2 2
                 : chr "020000100208" "020000100211" "020000100212" "020000100213" ...
   $ ncessch
##
    $ name
                  : chr "Bethel Regional High School" "Ayagina'ar Elitnaurvik" "Kwigillingok School" "N
                        "1006 Ron Edwards Memorial Dr" "106 Village Road" "108 Village Road" "118 Villa
## $ address
## $ city
                  : chr "Bethel" "Kongiganak" "Kwigillingok" "Toksook Bay" ...
  6. Use the names function to list the names of the elements (variables) within df_recruiting.
names(df_recruiting)
## [1] "state_code"
                      "school_type" "ncessch"
                                                   "name"
                                                                  "address"
## [6] "city"
  7. Wrap your answer above — names(data_frame_name) — within the typeof() function. Do the same
    for the length() function, and the str() function as well. Interpret what the output means in your
    own words.
typeof(names(df_recruiting))
## [1] "character"
length(names(df_recruiting))
## [1] 6
str(names(df_recruiting))
## chr [1:6] "state_code" "school_type" "ncessch" "name" "address" "city"
Answer: the names of the elements of the data frame object df_recruiting are a character atomic vector
of 6 elements
Question 4: Applying basic functions to atomic vectors
/9 pts
  1. Create an atomic vector object named age with the following values: 3, 6, 41, 43.
age < c(3,6,41,43)
  2. Apply the typeof(), length(), and str() functions to the object age.
typeof(age)
## [1] "double"
length(age)
## [1] 4
str(age)
## num [1:4] 3 6 41 43
  3. Apply the sum() function to age.
sum(age)
## [1] 93
```

4. Apply the sum() function to age but this time include the argument na.rm = FALSE.

```
sum(age, na.rm = FALSE)
```

[1] 93

5. In general, what is a function "argument name" and what is an "argument value"? What does the argument na.rm do?

Answer: When calling a function, the argument name tells R which argument you are referring to (e.g., the trim argument) and the argument value is the value you are assigning to that argument. the argument na.rm controls whether NA values are removed or not prior to performing calculations.

6. Create a new object age2 with the following values: 3, 6, 41, 43, NA. Now calculate the sum of age2 using the argument na.rm = FALSE and then calculate the sum using the argument na.rm = TRUE. Explain why the outputs of these two sum() functions differ.

```
age2 <- c(3,6,41,43,NA)
sum(age2, na.rm = FALSE)
## [1] NA
sum(age2, na.rm = TRUE)</pre>
```

[1] 93

Answer: The function sum(age2, na.rm = FALSE) returns NA because NA values are not removed prior to calculation and any calculation that includes an NA value returns NA. The function sum(age2, na.rm = TRUE) does not return NA because all NA values are removed prior to calculation.

7. Create a vector tf using the following code: tf <- c(TRUE,FALSE,TRUE,FALSE,TRUE). Next apply the typeof(), length(), and str() functions to the object tf. Based on this output, briefly describe the object tf in your own words (one sentence is fine).

```
tf <- c(TRUE,FALSE,TRUE,FALSE,TRUE,NA)

typeof(tf)

## [1] "logical"

length(tf)

## [1] 6

str(tf)</pre>
```

logi [1:6] TRUE FALSE TRUE FALSE TRUE NA

Answer: the object tf is an atomic vector of logical type with 5 elements.

8. Apply the sum() function to the object, using the option to remove NA values prior to calculation. What numeric value do mathematical calculations in R assign to TRUE values and what do they assign to FALSE values?

```
sum(tf, na.rm = TRUE)
```

[1] 3

Answer: Mathematical calculations in R assign the value of 0 to FALSE and the value of 1 to TRUE

9. This is the syntax of the mean() function that includes both argument names and the default values for arguments: mean(x, trim = 0, na.rm = FALSE).

When using a function, R requires you to type the values you assign to each argument, but typing in the argument names is usually optional. Even though it takes a bit more time, I usually like typing in both argument names and argument values, because it forces me to be more conscious about what value I am assigning to which argument, especially when a function is new to me.

Use the mean() function to calculate the mean of object tf (removing NA values prior to calculation). In your function call, include both the argument name and the argument value for each argument (argument value for the trim argument can be 0). Then run the same function, but without typing any argument names.

```
mean(x=tf, trim = 0, na.rm = TRUE)
## [1] 0.6
mean(tf, 0, TRUE)
## [1] 0.6
```

Question 5: Create a GitHub issue

/1 pts

- Go to the class repository and create a new issue.
- Refer to rclass1 student issues readme for instructions on how to post questions or reflections.
- You are also required to respond to at least one issue posted by another student.
- Paste the url to your issue here:
- Paste the url to the issue you responded to here:

Knit to pdf and submit problem set

Knit to pdf by clicking the "Knit" button near the top of your RStudio window (icon with blue yarn ball) or drop down and select "Knit to PDF".

- Go to the class website and under the "Readings & Assignments" » "Week 1" tab, click on the "Problem set 1 submission link".
- Submit both .Rmd and .pdf files.
- Use this naming convention "lastname_firstname_ps#" for your .Rmd and pdf files (e.g. jaquette_ozan_ps1.Rmd & jaquette_ozan_ps1.pdf).
